16. Abstract

This study was conducted to determine the effect of chord size on air cooled turbine blades. In the preliminary design phase, eight turbine blade cooling configurations in 0.75-in. (0.01905-m), 1.0-in. (0.0254-m), and 1.5-in. (0.0381-m) chord sizes were analyzed to determine the maximum turbine inlet temperature capabilities. A pin fin convection cooled configuration and a film-impingement cooled configuration were selected for a final design analysis in which the maximum turbine inlet temperature was determined as a function of the cooling air inlet temperature and the turbine inlet total pressure for each of the three chord sizes. The cooling air flow requirements were also determined for a varying cooling air inlet temperature with a constant turbine inlet temperature.

The conclusions of this study were that allowable turbine inlet temperature increases with increasing chord for the convection cooled and transpiration cooled designs, however, the film-convection cooled designs did not have a significant change in turbine inlet temperature with chord. The film-convection cooled designs allow turbine inlet temperatures about 200°F (111°K) higher than the convection cooled designs but the transpiration cooled design studied offered an advantage only for the 1.5-in. (0.0381-m) chord size. The turbine inlet pressure range studied had little effect on turbine inlet temperature capability, but a reduction in cooling air inlet temperature produced an increase in turbine inlet temperature capability or a reduction in cooling air flow required.

DETAILED BOUNDARY CONDITIONS, METAL TEMPERATURE DISTRIBUTION AND COOLING FLOW DISTRIBUTION FOR THE SCHEME A-I FINAL DESIGN ANALYSIS

The detailed boundary conditioms for the Scheme A-I Final Designs are shown in Figures J-I through J-36 for the 0.75 in. (0.01905 m), I.0 in. (0.0254 m), and I.5 in. (0.0381 m) chord blades. The boundary conditions include the relative total gas temperature, the effective film temperature where film cooling is applied, and the local external heat transfer coefficient at each element in the thermal model. The internal heat transfer coefficient and cooling air temperature distribution are also given in the boundary conditions. The boundary conditions are given for each of the three pressure levels 450 psia (3.1×10^6 Newtons/sq m), I50 psia (1.034×10^6 Newtons/sq m), and 50 psia (3.45×10^5 Newtons/sq m) for a cooling air inlet temperature of 900^0F (755.6^0K) and for the 1200^0F (922.2^0K) cooling air inlet temperature, 2100^0F (1422.2^0K) turbine inlet temperature condition.

The metal temperature distribution for each design point condition (900^0F (755.6^0K) cooling air inlet temperature and I50 psia (1.034×10^6 Newtons/sq m) turbine inlet total pressure) is given in Figures J-37 through J-45.

The cooling flow distribution at each cooling air inlet temperature with I50 psia (1.034×10^6 Newtons/sq m) turbine inlet pressure and at the additional condition of reduced cooling air inlet pressure is given in Figures J-46 through J-57.

APPENDIX K

DETAILED TEMPERATURES, STRESS, AND STRESS TO RUPTURE LIFE FOR EACH ELEMENT AND CREEP STRESS ANALYSIS RESULTS IN THE SCHEME A-1 FINAL DESIGN ANALYSIS

In the Final Design, Task I phase of the study, the convection cooled cast two cavity pin fin blade Scheme A-1 was studied in each of three chord sizes. The cooling configuration was modified as required to obtain the maximum turbine inlet temperature capability for a turbine inlet total pressure of 150 psia (1.034×10^6 Newtons/sq m) and a cooling air inlet temperature of 900^0F (755.6^0K). Cooling passage dimensions, trailing edge discharge holes, and flow control orifices were finalized to give the proper flow distribution for this condition. Using the Scheme A-1 blade, sized for the design point condition, the turbine inlet temperature capability for two off-design cooling air inlet temperatures and two off-design turbine inlet total pressures, was determined for each chord size.

Using a constant turbine inlet temperature determined for the 0.75 in. (0.01905 m) chord blade with a cooling air inlet temperature of 1200^0F (922.2^0K) and a turbine inlet total pressure of 150 psia (1.034×10^6 Newtons/sq m), the cooling airflow required as a function of the cooling air inlet temperature was determined for each chord size. These results were obtained by varying flow control orifice sizes only and maintaining a constant cooling passage dimension and trailing edge discharge hole size. Five additional conditions for the 1.0 in. (0.0254 m) chord blade were obtained by varying the trailing edge discharge and flow control orifice sizes to obtain the maximum turbine inlet temperature for three conditions, and to obtain the minimum cooling airflow required for two additional conditions.

A heat transfer analysis was conducted for each of these final design conditions at the hub (5 percent span), mean (50 percent span), and tip (75 percent span) sections of the blade. The analysis was performed using the AiResearch transient and steady state thermal analyzer computer program (H0910) described in Appendix B. The analysis includes the effects of the hot gas relative total temperature with a radial gas temperature correction factor; convection heat transfer from the hot gas to the blade surface; spanwise and chordwise conduction as well as conduction through the wall; internal convection heat transfer from the blade surface to the cooling air; and cooling air heatup due to heat addition and rotational acceleration. The internal convection heat transfer coefficients were calculated using the equations for transverse fins at the leading edge, pin fins in the center cavity, and entrance effects for the trailing edge discharge holes. Film cooling was applied at the trailing edge of the 0.75 in. (0.01905 m) chord design. Each of these techniques is described in the analytical methods section of this report.

The stress analysis was conducted for each element used in the thermal analysis at the hub, mean, and tip sections of the blade. The analysis was performed using the turbine blade elastic, inelastic, and creep stress analysis computer program (X0850) described in Appendix H. The initial stress at each

element of the blade was determined based on an elastic and plastic stress analysis including the effects of centrifugal loads, bending moments due to thermal distortions and local plastic flow of the material. For the blade designs in which the initial stress distribution was critical, a creep relaxation analysis was performed to determine the time to 1 percent creep strain for the critical elements of the blade.

The centrifugal loads for each of the blades include the effects of the dead weight of the fins and the tip cap for the 1.0 in. (0.0254 m) and 1.5 in. (0.0381 m) chord blade. Gas bending loads were neglected because these loads are small and may be cancelled out by tilting the blades. Bending moments due to offsetting the line of action of the centrifugal force as a result of thermal distortion and relaxation of stress due to local instantaneous plastic flow of the material are considered in AiResearch computer program X0850. The creep relaxation analysis was performed according to the strain-hardening procedure described in Appendix H. The life tabulated at each element of the blade was calculated for the initial stress distribution from the minimum design curve of the master stress-rupture curve for IN-100 material. The stress life of each blade is determined by the time required for the critical element of the blade to reach 1 percent creep strain after stress redistribution due to creep. The life of each turbine blade is also limited by a maximum coating temperature limit of 1840°F (1277.8°K) for 1000 hr life.

The metal temperatures, initial stress, and the stress to rupture life based on the initial stress distribution before creep relaxation is given for each element at each condition in the following tables. Half of the conditions are limited by a maximum metal temperature of 1840°F (1277.8°K) for 1000 hr life with IN-100 material. The other conditions were limited by the time to 1 percent creep strain for the critical elements of the blade. Where it was obvious from initial stress distribution analysis, that the condition would be limited by maximum metal temperature, a creep stress analysis was not necessary. The initial stress distribution for conditions in which a creep stress analysis had been performed was used to estimate the time to 1 percent creep strain for other conditions with similar initial stress distribution results. Therefore, a creep stress relaxation analysis was performed for only the most critical stress conditions and the results were used to determine life at other conditions by comparison of initial stress distribution analysis results. The creep strain and the element stress as a function of time are shown in Figures K-1, K-2, K-3, K-5, K-6, K-7, K-10, K-11 and K-12 for the critical elements of the critical stress conditions. The element numbers in each table and figure refer to the numbered locations at the hub, mean, and tip sections of the blade shown in Figures K-4, K-8, K-9, K-13, and K-14 (the foldout pages). The condition numbers referred to in these tables are for identification of the hub, mean, and tip section results of each final design analysis. The conditions of each final design analysis are summarized in Table K-1. The symbol TIT refers to hot gas turbine inlet total temperature, the symbol WCA refers to the total cooling air flow rate for the blade, the symbol TCA refers to the cooling air inlet total temperature at the blade root, and the symbol PTOT refers to the hot gas turbine inlet total pressure. The symbol W_{CLE} refers to the cooling air flow through the leading edge cavity, the symbol W_{CM} refers to the cooling air flow entering the pin passage at the base of the blade, and the symbol W_{CTE} refers to the cooling air

flow discharging from the pin fin passage through the trailing edge holes. The stress levels presented in the tables of this appendix are in psi and the metal temperatures are in ^{0}F.

FIGURE K-14. SCHEME A-1 CONVECTION COOLED CAST TWO-CAVITY PIN FIN BLADE 1.5 INCH CHORD

APPENDIX L

DETAILED BOUNDARY CONDITIONS, METAL TEMPERATURE DISTRIBUTION, AND COOLING FLOW DISTRIBUTION FOR THE SCHEME B-5 FINAL DESIGN ANALYSIS

The detailed boundary conditions for the Scheme B-5 Final Designs are shown in Figures L-1 through L-36 for the 0.75 in. (0.01905 m), 1.0 in. (0.0254 m), and 1.5 in. (0.0381 m) chord blades. The boundary conditions include the relative total gas temperature, the effective film temperature where film cooling is applied, and the local external heat transfer coefficient at each element in the thermal model. The internal heat transfer coefficient and cooling air temperature distribution are also given in the boundary conditions. The boundary conditions are given for each of the three pressure levels 450 psia (3.1×10^6 Newtons/sq m), 150 psia (1.034×10^6 Newtons/sq m), and 50 psia (3.45×10^5 Newtons/sq m) for a cooling air inlet temperature of 900°F (755.6°K) and for the 1200°F (922.2°K) cooling air inlet temperature, and 2320°F (1543°K) turbine inlet temperature condition.

In Figures L-1 through L-36, the hot gas heat transfer coefficient on the outer surface of the blade is presented without parentheses and the cooling air heat transfer coefficient is presented with parentheses. The effective hot gas temperature due to film cooling is presented with brackets and the cooling air temperature is presented in double parentheses. The asterisk (*) beside any of the symbols indicates that the conditions exist on the cooling air impingement supply tube. The heat transfer coefficient on inner blade surface is high due to impingement, but the outer surface of the supply tube is only exposed to forced convection from the spent impingement cooling air and, therefore, has a low heat transfer coefficient. Where the element is located in an area where a separator exists, the letter (f) is used to designate conditions forward or toward the leading edge of the separator and the letter (a) is used to designate conditions aft, or toward the trailing edge, of the separator.

The metal temperature distribution for each design point condition (900°F (755.6°K) cooling air inlet temperature and 150 psia (1.034×10^6 Newtons/sq m) turbine inlet total pressure) is given in Figures L-37 through L-45.

The cooling air flow distribution at each cooling air inlet temperature with 150 psia (1.034×10^6 Newtons/ sq m) turbine inlet pressure and at the additional condition of reduced cooling air inlet pressure is given in Figures L-46 through L-57.

APPENDIX M

DETAILED TEMPERATURES, STRESS, AND STRESS TO RUPTURE LIFE FOR EACH ELEMENT AND CREEP STRESS ANALYSIS RESULTS IN THE SCHEME B-5 FINAL DESIGN ANALYSIS

In the Final Design, Task I phase of the study, the film-convection cooled fabricated impingement tube blade scheme B-5 was studied in each of three chord sizes. The cooling configuration was modified as required to obtain the maximum turbine inlet temperature capability for a turbine inlet total pressure of 150 psia (1.034×10^6 Newtons/sq m) and a cooling air inlet temperature of 900°F (755.6°K). The cooling passage dimensions, impingement holes, film cooling holes, trailing edge discharge holes, and flow control orifices were finalized to give the proper flow distribution for this condition. Using the scheme B-5 blade sized for the design point condition, the turbine inlet temperature capability for two off-design cooling air inlet temperatures and two off-design turbine inlet total pressures was determined for each chord size.

Using a constant turbine inlet temperature determined for the 0.75 in. (0.01905 m) chord blade with a cooling air inlet temperature of 1200°F (922.2°K) and a turbine inlet total pressure of 150 psia (1.034×10^6 Newtons/sq m), the cooling air flow required, as a function of the cooling air inlet temperature, was determined for each chord size. These results were obtained by varying flow control orifice sizes only and maintaining a constant cooling passage dimension and trailing edge discharge hole size. Five additional conditions for the 1.0 in.(0.0254 m) chord blade were obtained by varying trailing edge discharge and flow control orifice sizes to obtain maximum turbine inlet temperature for three conditions and to obtain minimum cooling air flow required for two additional conditions.

A heat transfer analysis was conducted for each of these final design conditions at the hub (five percent span), mean (50 percent span), and tip (75 percent span) sections of the blade. The analysis was performed using the AiResearch transient and steady state thermal analyzer computer program (H0910) described in Appendix B. The analysis includes the effects of the hot gas relative total temperature with a radial gas temperature correction factor; convection heat transfer from the hot gas to the blade surface; spanwise and chordwise conduction as well as conduction through the wall; internal convection heat transfer from the blade surface to the cooling air; and cooling air heatup due to heat addition and rotational acceleration. The internal convection heat transfer coefficients were calculated using the equations for impingement at the leading edge, impingement with crossflow in the center cavity, and entrance effects for the trailing edge discharge holes. Film cooling was applied at the leading and trailing edges of the blades. Each of these techniques is described in the analytical methods section of this report.

The stress analysis was conducted for each element used in the thermal analysis at the hub, mean, and tip sections of the blade. The analysis was performed using the turbine blade elastic, inelastic, and creep stress analysis computer program (X0850) described in Appendix H. The initial stress at each element of the blade was determined based on an elastic and plastic stress analysis including the effects of centrifugal loads, bending moments due to thermal distortion, and local plastic flow of the material. For the blade designs in which the initial stress distribution was critical, a creep relaxation analysis was performed to determine the time to 1 percent creep strain for the critical elements of the blade.

The centrifugal loads for each of the blades includes the effects of the dead weight of the fins and the tip cap. Gas bending loads were neglected because these loads are small and may be cancelled out by tilting the blades. Bending moments due to offsetting the line of action of the centrifugal force as a result of thermal distortion and relaxation of stress due to local instantaneous plastic flow of the material are considered in AiResearch computer program X0850. The creep relaxation analysis was performed according to the strain-hardening procedure described in Appendix H. The life tabulated at each element of the blade was calculated for the initial stress distribution from the minimum design curve of the master stress-rupture curve for IN-100 material. The stress life of each blade is determined by the time required to reach the 1 percent creep strain after critical stress redistribution due to creep for the critical element of the blade. The life of each turbine blade is also limited by a maximum coating temperature limit of 1840°F (1277.8°K) for 1000 hr life.

The metal temperatures, initial stress, and the stress to rupture life based on the initial stress distribution before creep relaxation is given for each element at each condition in the following tables. Some of the conditions are limited by a maximum metal temperature of 1840°F (1277.8°K) for 1000 hr life with IN-100 material. Other conditions were limited by the time to 1 percent creep strain for the critical elements of the blade. Where it was obvious from initial stress distribution analysis that the condition would be limited by maximum metal temperature, a creep stress analysis was not necessary. The initial stress distribution for conditions in which a creep stress analysis had been performed was used to estimate the time to 1 percent creep strain for other conditions with similar initial stress distribution results. Therefore, a creep stress relaxation analysis was performed for only the most critical stress conditions and the results were used to determine life at other conditions by comparison of initial stress distribution analysis results. The creep strain and the element stress as a function of time are shown in Figures M-1, M-2, M-3, M-5, M-6, M-7, M-8, M-9, M-11, M-12, and M-13 for the critical elements of the critical stress conditions. The element numbers in each table and figure refer to the numbered locations at the hub, mean, and tip sections of the blade shown in Figures M-4, M-10, and M-14 (the foldout pages). The condition numbers referred to in these tables are for identification of the hub, mean, and tip section results of each final design analysis. The conditions of each final design analysis are summarized in Table M-1. The symbol TIT refers to the hot gas turbine inlet total temperature, the symbol WCA refers to the total cooling air flow rate from the blade, the symbol TCA refers to the cooling air inlet total temperature at

the blade root, and the symbol PTOT refers to the hot gas turbine inlet total pressure. The cooling air flow distribution is expressed as the cooling air flow for one third of the blade span allocated to each area of the blade. The symbol W_{CLE} refers to the flow from the impingement tube to the leading edge; The symbol W_{CAP} refers to the flow from the impingement tube to the pressure side of the blade; the symbol W_{CAS} refers to the flow from the impingement tube to the pressure side of the blade; the symbol W_{CAS} refers to the flow from the impingement tube to the suction side of the blade, and the symbol W_{CTE} refers to the flow from the impingement tube to the trailing edge of the blade. The stress levels presented in the tables of this appendix are in psi and the metal temperatures are in ^{0}F.

TABLE M-1

SUMMARY OF FINAL DESIGN ANALYSIS CONDITIONS FOR THE SCHEME B-5 FILM-CONVECTION COOLED FABRICATED IMPINGEMENT TUBE BLADE
